Abstract

The decays $D_s^\pm \rightarrow \mu^\pm \nu_\mu$ and $D_s^\pm \rightarrow \tau^\pm \nu_\tau$ have traditionally been used to measure the D_s^\pm meson decay constant f_{D_s} . Recent measurements at CLEO-c and the B factories suggest a branching ratio for both decays somewhat higher than the Standard Model prediction using f_{D_s} from unquenched lattice calculations. The charged Higgs boson (H^\pm) in the Two Higgs Doublet Model (Type II) would also mediate these decays, but any sizeable contribution from H^\pm can only suppress the branching ratios and consequently is now slightly disfavoured. It is shown that constraints on the parameters $\tan \beta$ and m_{H^\pm} from such decays can be competitive with and complementary to analogous constraints derived from the leptonic meson decays $B^\pm \rightarrow \tau^\pm \nu_\tau$ and $K^\pm \rightarrow \mu^\pm \nu_\mu$, especially if lattice calculations eventually prefer $f_{D_s} < 250$ MeV.

1 Introduction

In the Standard Model (SM) the purely leptonic decays of charged pseudoscalar mesons ($P^\pm \rightarrow \ell^\pm \nu$) proceed via annihilation in the s -channel to a W boson. The decay rates are proportional to the lepton mass m_ℓ which arises from the chirality flip of the lepton required to conserve angular momentum. Such decays have traditionally been used to measure the decay constants of the pseudoscalar mesons, and thus provide an important test of lattice Quantum Chromodynamics (QCD) calculations. The unprecedented data

samples provided by the B factories have enabled the decay $B^\pm \rightarrow \tau^\pm \nu$ to be observed [1, 2, 3, 4] despite its relatively small branching ratio (BR) and challenging signature. The decays $D^\pm \rightarrow \mu^\pm \nu$ [5, 6], $D_s^\pm \rightarrow \mu^\pm \nu$ [7, 8, 9] and $D_s^\pm \rightarrow \tau^\pm \nu$ [7, 9, 10, 11] have been measured with $\sim 10\%$ precision at CLEO-c, and the recently commenced BES-III experiment will provide improved measurements [12, 13]. Moreover, the decay $D_s^\pm \rightarrow \mu^\pm \nu$ has been measured at the B factories [14, 15] with a precision slightly less than that of CLEO-c.

These purely leptonic decays are sensitive to charged Higgs boson (H^\pm) at the tree level and thus provide valuable probes of such particles which are complementary to constraints provided by loop-induced decays (e.g., $b \rightarrow s\gamma$). Importantly, in supersymmetric (SUSY) models the loop-induced decays are particularly sensitive to the sparticle spectrum and the assumptions made for the SUSY breaking sector, and thus the purely leptonic decays offer a more model-independent probe of parameters in the Higgs sector. The measurement of $B^\pm \rightarrow \tau^\pm \nu$ [1, 3], although in rough agreement with the SM prediction, provides important constraints on the mass and couplings of H^\pm from the Two Higgs Doublet Model (Type II) [16], with some dependence on SUSY parameters [17, 18, 19, 20, 21, 22] which enters at higher orders in perturbation theory. Improved measurements of $B^\pm \rightarrow \tau^\pm \nu$ (and first observation of $B^\pm \rightarrow \mu^\pm \nu$) are thus certainly desirable and such decays play a prominent role in the physics case for a high luminosity flavour factory [23, 24, 25, 26, 27, 28, 29, 30, 31].

The decay rates of $D^\pm \rightarrow \mu^\pm \nu$ and $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ have traditionally been considered as a robust test of lattice QCD calculations of the decay constants f_D and f_{D_s} because significant New Physics effects were thought to be unlikely. However, the effect of H^\pm on $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ was pointed out to be non-negligible in [16, 32, 33] and a numerical study [34, 35] showed that the magnitude of the H^\pm contribution can be comparable to both the CLEO-c error and the lattice QCD error for the decay constants. SUSY particles from models with R -parity violating interactions can also contribute to both $D^\pm \rightarrow \mu^\pm \nu$ and $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ [36]. Recently, there has been growing interest in the effect of New Physics particles on $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ [37] because the current world average of the experimental measurements of their branching ratios is somewhat higher than the SM rate using unquenched lattice QCD calculations of f_{D_s} [38, 39]. Such a discrepancy cannot be explained by H^\pm of the popular Two Higgs Doublet Model (Type II) since any sizeable contribution (which arises from a relatively large strange quark Yukawa coupling) can only suppress the decay rate [16, 32, 34, 35]. In this paper we consider in detail the effect of H^\pm on $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ using the program SuperIso [40, 41]. It is shown that constraints derived on the plane $[\tan \beta, m_{H^\pm}]$ can be competitive with the constraints obtained from the analogous leptonic decays $B^\pm \rightarrow \tau^\pm \nu$ and $K^\pm \rightarrow \mu^\pm \nu$. In particular, we compare the potential of $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ and $K^\pm \rightarrow \mu^\pm \nu$ [42, 43, 44] to probe the plane $[\tan \beta, m_{H^\pm}]$.

The paper is organized as follows: in section 2 the theoretical formalism for the decays $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ and $K^\pm \rightarrow \mu^\pm \nu$ is introduced; numerical results are contained in section 3 with conclusions in section 4.

2 Effect of H^\pm on leptonic decays of D_s^\pm and K^\pm

In this section we review the theoretical formalism for the effect of H^\pm on $D_s^\pm \rightarrow \mu^\pm \nu$, $D_s^\pm \rightarrow \tau^\pm \nu$ and $K^\pm \rightarrow \mu^\pm \nu$, and summarize the experimental situation.

2.1 The decays $D_s^\pm \rightarrow \mu^\pm \nu$ and $D_s^\pm \rightarrow \tau^\pm \nu$

In the SM the purely leptonic decays $D_s^\pm \rightarrow \ell^\pm \nu_\ell$ proceed via annihilation of the heavy meson into W^* . Singly charged Higgs bosons, which arise in any extension of the SM with at least two $SU(2)_L \times U(1)_Y$ Higgs doublets with hypercharge $Y = 1$, would also contribute to these decays [16]. The tree-level partial width is given by (where $\ell = e, \mu$ or τ):

$$\Gamma(D_s^\pm \rightarrow \ell^\pm \nu_\ell) = \frac{G_F^2}{8\pi} f_{D_s}^2 m_\ell^2 M_{D_s} \left(1 - \frac{m_\ell^2}{M_{D_s}^2}\right)^2 |V_{cs}|^2 r_s, \quad (1)$$

where in the Two Higgs Doublet Model (2HDM) of Type II [16, 32, 35, 37, 38]:

$$r_s = \left[1 + \left(\frac{1}{m_c + m_s} \right) \left(\frac{M_{D_s}}{m_{H^+}} \right)^2 \left(m_c - \frac{m_s \tan^2 \beta}{1 + \epsilon_0 \tan \beta} \right) \right]^2. \quad (2)$$

Here m_c and m_s are the masses of the charm and strange quarks respectively, m_{H^+} is the mass of the charged Higgs boson, M_{D_s} is the mass of the D_s^\pm meson, $\tan \beta = v_2/v_1$ where v_1 and v_2 are the vacuum expectation values of the two scalar doublets, V_{cs} is a Cabibbo-Kobayashi-Maskawa (CKM) matrix element, m_ℓ is the lepton mass and G_F is the Fermi constant. In the 2HDM (Type II) each fermion receives mass from one vacuum expectation value (v_1 or v_2) at tree level and consequently $\epsilon_0 = 0$. In the 2HDM (Type III) each fermion receives a mass from both v_1 and v_2 and the term $\epsilon_0 \neq 0$ must be included. The Yukawa couplings of the Minimal Supersymmetric SM (MSSM) take the form of a 2HDM (Type II) at tree level, but at higher orders the structure becomes of the type 2HDM (Type III) in which ϵ_0 is a function of SUSY parameters [45, 46, 47, 48] and $|\epsilon_0|$ can reach values of order 0.01.

The above formula Eq. (2) was derived in [16] for $\epsilon_0 = 0$ and neglecting the term m_c in $(m_c - m_s \tan^2 \beta)$. This m_c term originates from the charm quark Yukawa coupling and increases r_s (and was included in [32]) but its magnitude is numerically tiny and can be neglected given the current experimental and theoretical errors. The term $m_s \tan^2 \beta$, which originates from the strange quark Yukawa coupling, can give rise to a non-negligible suppression of r_s for large values of $\tan \beta$. Both [16] and [32] neglected m_s when it appears as $(m_c + m_s)$ and this correction was first included in [35]. The above complete expression for the case of $\epsilon_0 = 0$ is taken from [37, 38]. The ϵ_0 correction can be non-negligible for large $\tan \beta$ and should be included in a dedicated study of r_s in the context of the MSSM. The parameterization of the ϵ_0 correction in Eq. (2) is valid in MSSM models with minimal flavour violation. We neglect to write explicitly the analogous ϵ_0 correction for the m_c term since this correction does not have the $\tan \beta$ enhancement factor, and the m_c term is negligible anyway. A first quantitative study of the magnitude of r_s (setting $\epsilon_0 = 0$)

was performed in [34, 35] for the $m_s \tan^2 \beta$ term only and it was shown that r_s could be suppressed by an amount comparable to both the CLEO-c experimental precision and the theoretical error in the lattice calculations of f_{D_s} . Note that the magnitude of the H^\pm contribution depends on the ratio of quark masses $m_s/(m_c + m_s)$, and an analogous uncertainty is not present for the H^\pm contribution to the decay $B^\pm \rightarrow \ell^\pm \nu$.

There are various unquenched lattice calculations of f_{D_s} and the current situation is summarized in [38] and updated in [9, 49]. The value with the smallest quoted error is $f_{D_s} = 241 \pm 3$ MeV [50] which employs staggered fermions. Another calculation with staggered fermions gives $f_{D_s} = 249 \pm 11$ MeV [49, 51]. Other calculations use different lattice techniques and have larger errors than that of [50], although usually with a central value less than 250 MeV (e.g., $248 \pm 3 \pm 8$ MeV [52]). On the experimental side, $D_s^\pm \rightarrow \tau^\pm \nu$ has been measured at CLEO-c for two decay modes of τ [9, 11] and $D_s^\pm \rightarrow \mu^\pm \nu$ has been measured at CLEO-c [9], BELLE [14] and BABAR [15]. Taking an average of these measurements (excluding the BABAR result which has an additional error from normalizing to the branching ratio of $D_s^\pm \rightarrow \phi^0 \pi^\pm$) results in an unexpectedly high value of $f_{D_s} = 261 \pm 7$ MeV (derived in [9] and is dominated by the average of the three CLEO-c measurements in [9] and [11]). A previous average gave $f_{D_s} = 273 \pm 10$ MeV [38, 39]. The sizeable difference between this world average measurement of f_{D_s} and the lattice QCD value with smallest error ($f_{D_s} = 241 \pm 3$ MeV [50]) has brought attention to the effect of New Physics particles on these decays [37]. As discussed above, H^\pm in the 2HDM (Model II) can only give a sizeable *suppression* of the branching ratio for $D_s^\pm \rightarrow \mu^\pm \nu, \tau^\pm \nu$, and not a sizeable enhancement. Candidate models which can enhance the BRs sufficiently are R -parity violating models [36, 37, 53] or models with leptoquarks [37, 54]. We note that the scenario of a charged Higgs boson from an unconventional 2HDM with a large charm quark Yukawa coupling [37] (which is never possible in standard 2HDMs in which the top and charm quark receive mass from the same vacuum expectation value) was also available to accommodate the data for $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu)$. However, such a H^\pm would enhance $\text{BR}(D^\pm \rightarrow \mu^\pm \nu)$ by the same amount [55] and now appears to be disfavoured by the final CLEO-c measurement of $\text{BR}(D^\pm \rightarrow \mu^\pm \nu)$ and f_D [6], which is in good agreement with the lattice calculation of f_D in [50].

In [56] two lattice QCD calculations [50, 51] of f_{D_s} were combined with the value obtained from QCD spectral sum rules in order to give an average value of f_{D_s} . Moreover, an analogous average of calculations of f_D and f_{D_s}/f_D were multiplied together to give an independent evaluation of f_{D_s} . The above procedure gives the value $f_{D_s} = 240 \pm 7$ MeV (i.e. very similar to $f_{D_s} = 241 \pm 3$ MeV of [50]). The consequences of relaxing the assumption of unitarity of the CKM matrix when extracting the measurement of f_{D_s} from $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu)$ were also discussed. In the models we study in this work (2HDM and MSSM) the CKM matrix is unitary and $|V_{cs}| \sim |V_{ud}|$ with very small error. As discussed in [56], this scenario leads to the largest discrepancy between the experimental and theoretical values of f_{D_s} .

In order to make conclusive statements about the possibility of New Physics enhancing $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ it is evident that a detailed discussion of the errors for the value of f_{D_s} evaluated in [50] is required, as well as a consensus in the lattice community concerning

the magnitude of the error. Our view is that the current situation of the world average measurement of f_{D_s} being higher than most lattice calculations of f_{D_s} is provocative and certainly merits attention because more precise measurements of $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ will be possible at the recently commenced BES-III experiment [12]. In addition, high luminosity flavour factories are also being discussed [23] which have the option of running at the charm threshold [57] with data samples even larger than those anticipated at BES-III. In this work our aim is not to explain the currently higher than expected $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu)$ by invoking specific New Physics models. Indeed, one cannot predict the preferred values for the lattice calculations of f_{D_s} although one expects a gradual decrease of the error. The current discrepancy between the experimental and lattice QCD values for f_{D_s} might persist, worsen or disappear entirely. Instead, we wish to emphasize that $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu)$ should be considered seriously as a process which potentially offers constraints on models containing a H^\pm with the popular structure of the 2HDM (Type II), which includes the MSSM.

In [38, 39] the SM prediction for $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu_\mu/\tau^\pm \nu_\tau)$ using the lattice calculation with smallest error ($f_{D_s} = 241 \pm 3$ MeV [50]) was compared with the experimental world average at the time for f_{D_s} (273 ± 10 MeV). It was concluded that any H^\pm contribution is disfavoured at more than 3σ . Such a result shows the potentially important role of the decays $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ as a probe of H^\pm . However, it is also clear that constraints on H^\pm derived from these decays are strongly dependent on the central value and error for the lattice calculation of f_{D_s} and so should be interpreted with caution at present. In this work we aim to quantify the constraints on the plane $[\tan \beta, m_{H^\pm}]$ from $D_s^\pm \rightarrow \mu^\pm \nu_\mu/\tau^\pm \nu_\tau$ with various assumptions for the central value and error of the lattice QCD calculation of f_{D_s} , and compare the constraints to those obtained from other decays which are sensitive to H^\pm .

2.2 The decay $K^\pm \rightarrow \mu^\pm \nu$

A decay which has many similarities with $D_s^\pm \rightarrow \mu^\pm \nu$ and $D_s^\pm \rightarrow \tau^\pm \nu$ is $K^\pm \rightarrow \mu^\pm \nu$. This decay can also be mediated by H^\pm of the 2HDM (Type II) at tree level [16] with a scale factor similar to that in Eq. (2). In order to reduce the theoretical uncertainties from the decay constant f_K , the ratio of partial widths is usually considered:

$$\begin{aligned} \frac{\Gamma(K^\pm \rightarrow \mu^\pm \nu_\mu)}{\Gamma(\pi^\pm \rightarrow \mu^\pm \nu_\mu)} &= \left| \frac{V_{us}}{V_{ud}} \right|^2 \frac{f_K^2 m_K}{f_\pi^2 m_\pi} \left(\frac{1 - m_\ell^2/m_K^2}{1 - m_\ell^2/m_\pi^2} \right)^2 \\ &\times \left(1 - \frac{m_{K^\pm}^2}{m_{H^\pm}^2} \left(1 - \frac{m_d}{m_s} \right) \frac{\tan^2 \beta}{1 + \epsilon_0 \tan \beta} \right)^2 (1 + \delta_{\text{em}}). \end{aligned} \quad (3)$$

Here $\delta_{\text{em}} = 0.0070 \pm 0.0035$ is a long distance electromagnetic correction factor. As suggested in [42], we study instead the quantity

$$R_{\ell 23} \equiv \left| \frac{V_{us}(K_{\ell 2})}{V_{us}(K_{\ell 3})} \times \frac{V_{ud}(0^+ \rightarrow 0^+)}{V_{ud}(\pi_{\ell 2})} \right|. \quad (4)$$

Here $V_{us}(K_{\ell i})$ refers to V_{us} as measured in leptonic decay of K^\pm with i particles in the final state (two leptons and a number of pions), and similarly for V_{ud} . $V_{ud}(0^+ \rightarrow 0^+)$ denotes V_{ud} measured from nuclear beta decay. In the SM $R_{\ell 23} = 1$, while the contribution from H^\pm in the MSSM attains the simple form (which can be compared to Eq. (2)):

$$R_{\ell 23} = \left| 1 - \frac{m_{K^\pm}^2}{m_{H^\pm}^2} \left(1 - \frac{m_d}{m_s} \right) \frac{\tan^2 \beta}{1 + \epsilon_0 \tan \beta} \right|. \quad (5)$$

Using $m_d/m_s = 1/20$ [39], the MSSM prediction can be directly compared to the experimental value [42]

$$R_{\ell 23} = 1.004 \pm 0.007. \quad (6)$$

In the extraction of this value, the ratio f_K/f_π has been fixed to the value $f_K/f_\pi = 1.189 \pm 0.007$ obtained from lattice QCD using staggered quarks [50]. It should be noted that the uncertainty thus obtained for $R_{\ell 23}$ is most probably overly optimistic. Indeed, many approaches exist to determine f_K/f_π , and some reservations remain about staggered fermions despite their impressive success in agreeing with the experimental values of various “gold-plated” observables in flavour physics (e.g., contrasting opinions concerning their theoretical viability are expressed in [58] and [59]). If, for example, the value $f_K/f_\pi = 1.205 \pm 0.018$ (obtained using the domain wall formulation [60]) is used instead, then $R_{\ell 23}$ provides no constraints on the plane $[\tan \beta, m_{H^\pm}]$ [44]. A recent analysis in [61] used $f_K/f_\pi = 1.19 \pm 0.015$ and also found very weak constraints. We therefore stress that the constraints obtained from Eq. (6), although certainly valuable due to their sensitivity to H^\pm at tree level, should serve only as an indication of the potential of K^\pm decays to probe the plane $[\tan \beta, m_{H^\pm}]$. It is our aim to compare such constraints in this optimum scenario for $R_{\ell 23}$ (i.e. using the lattice calculations of [50]) with those derived from $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$. We note that $R_{\ell 23}$ also requires lattice QCD input for the semi-leptonic kaon decay form factor f_+ , while the decays $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$ rely on lattice QCD only for f_{D_s} . The direct measurement of V_{us} (relevant for $R_{\ell 23}$) is much more precise than that for V_{cs} (relevant for $D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu$). However, V_{cs} can be taken as a well-measured parameter by assuming a unitary CKM matrix, which is the case for the models we study.

3 Numerical Analysis

The branching ratios for $D_s^\pm \rightarrow \tau^\pm \nu_\tau$ and $D_s^\pm \rightarrow \mu^\pm \nu_\mu$ have been implemented in SuperIso [40, 41] following Eqs. (1) and (2). The ϵ_0 correction for the second quark generation has also been added to take into account the SUSY effect. This effect has been neglected in all previous studies of $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu_\tau)$ and $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu_\mu)$.

To illustrate the constraining power of these observables, we consider the MSSM with minimal flavour violation (MFV), and in particular the Non-Universal Higgs Mass model (NUHM). The NUHM assumes SUSY breaking mediated by gravity and is characterized by a set of universal parameters at the GUT scale $\{m_0, m_{1/2}, A_0, \tan \beta, \mu, M_A\}$. The first four parameters in this set are the same as in CMSSM (or mSUGRA), but the GUT scale mass parameter universality is relaxed for the Higgs sector leading to two additional

parameters, μ and M_A , which implies in particular that the charged Higgs mass can be considered as a free parameter. This additional freedom makes this model attractive for studying the constraints on the Higgs sector.

To investigate the NUHM parameter space we generate 50,000 random points scanning over the ranges $m_0 \in [50, 2000]$ GeV, $m_{1/2} \in [50, 2000]$ GeV, $A_0 \in [-2000, 2000]$ GeV, $\mu \in [-2000, 2000]$ GeV, $m_A \in [5, 600]$ GeV and $\tan \beta \in [1, 60]$. For each point we calculate the spectrum of SUSY particle masses and couplings using SOFTSUSY 2.0.18 [62] and we compute the branching fractions $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu_\tau)$, $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu_\mu)$ and $\text{BR}(K^\pm \rightarrow \mu^\pm \nu_\mu)$ using SuperIso v2.4 [41]. The obtained values are then compared to the experimentally allowed intervals while taking uncertainties in consideration.

The PDG08 [39] combined experimental results for the branching fractions of $D_s^\pm \rightarrow \tau^\pm \nu$ and $D_s^\pm \rightarrow \mu^\pm \nu$ are:

$$\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu) = (6.6 \pm 0.6) \times 10^{-2}, \quad (7)$$

$$\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu) = (6.2 \pm 0.6) \times 10^{-3}. \quad (8)$$

The final CLEO-c results using 600 pb^{-1} have been recently released [9, 11] and give smaller central values and errors:

$$\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu) = (5.65 \pm 0.45 \pm 0.17) \times 10^{-3}, \quad (9)$$

$$\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu) = (5.62 \pm 0.41 \pm 0.16) \times 10^{-2}. \quad (10)$$

For $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ the average in Eq. (7) is from the measurements of [7, 63, 64, 65]. In order to have an updated world average we replace the previous CLEO-c measurement of [7] by the new measurement [9, 11] to obtain:

$$\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu) = (5.7 \pm 0.4) \times 10^{-2}. \quad (11)$$

For $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ the constraints on the plane $[\tan \beta, m_{H^\pm}]$ turn out to be weaker than those from $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$. Therefore for illustration and comparison we only average over the CLEO-c [9] and BELLE [14] measurements of $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ (as suggested in [38, 39]) which are the only measurements without an additional error from normalizing to the branching ratio of $D_s^\pm \rightarrow \phi^0 \pi^\pm$. Our average is:

$$\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu) = (5.8 \pm 0.4) \times 10^{-3}. \quad (12)$$

In our numerical analysis we employ the lattice calculation of the D_s^\pm decay constant with smallest error [50] in order to give the SM prediction for the branching ratios:

$$f_{D_s} = 241 \pm 3 \text{ MeV}, \quad (13)$$

$$\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu) = (4.82 \pm 0.14) \times 10^{-2}, \quad (14)$$

$$\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu) = (4.98 \pm 0.15) \times 10^{-3}. \quad (15)$$

We will comment qualitatively on the case of using a different value with a larger error.

We use the most up-to-date PDG08 values for the quark masses [39]:

$$m_s = 104^{+26}_{-34} \text{ MeV} \quad m_c = 1.27^{+0.07}_{-0.11} \text{ GeV} . \quad (16)$$

To take into account this uncertainty we vary the ratio m_s/m_c in the interval [0.04,0.12] with $m_s/m_c = 0.08$ being the central value.

An estimation of the total theoretical error in the decay rates (Eq. 1) yields about 3% relative uncertainty. The dominant theoretical error is from the lattice evaluation of f_{D_s} , while the error from V_{cs} is very small if CKM unitarity is assumed (which is the case in the models which we study). The errors from SUSY and other parameters in Eq. (1) yield less than 1% relative uncertainty. In order to undertake a slightly conservative approach we consider 4% relative theoretical uncertainty in our numerical analysis. Eqs. (11) and (12) lead to the following allowed intervals at 95% C.L. for $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$:

$$4.8 \times 10^{-2} < \text{BR}(D_s^\pm \rightarrow \tau^\pm \nu) < 6.6 \times 10^{-2} , \quad (17)$$

and for $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$

$$4.9 \times 10^{-3} < \text{BR}(D_s^\pm \rightarrow \mu^\pm \nu) < 6.7 \times 10^{-3} , \quad (18)$$

in which both experimental and theoretical errors are included, as in the analysis of [44].

Fig. 1 illustrates the obtained constraints by a projection of the six dimensional NUHM parameter space onto the plane $[\tan \beta, m_{H^\pm}]$. The allowed points are displayed in the foreground in green while the points excluded by $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ at 95% C.L are displayed in the background in red. The results for three choices of m_s/m_c are presented. A large part of the parameter plane is excluded even for the pessimistic case of $m_s/m_c = 0.04$. The region where red and green points overlap is caused by the theoretical uncertainty (mainly arising from f_{D_s}) and from the effect of the ϵ_0 term which may take either sign and depends on all six NUHM parameters.

In Fig. 2 the points excluded by $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ are shown in black for the same three choices of m_s/m_c . The obtained constraints are less severe in this case since the predicted SM value is closer to the central experimental value for $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ than for $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$.

In order to compare our results with the constraints from $K^\pm \rightarrow \mu^\pm \nu$, we present in Fig. 3 the points excluded at 95% C.L. by the $R_{\ell 23}$ observable using the range given by Eq. (6) with no additional error, which is probably overly optimistic as discussed in [44] and in section 2.2. It is clear that $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ is more powerful at constraining the plane $[\tan \beta, m_{H^\pm}]$ than $R_{\ell 23}$ even for the pessimistic case of $m_s/m_c = 0.04$ (likewise for $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ if $m_s/m_c > 0.04$). Although $R_{\ell 23}$ has less uncertainty from quark mass parameters than $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu)$ (i.e., the theoretical uncertainty from m_d/m_s is less than that from m_s/m_c) we stress that the pessimistic case of $m_s/m_c = 0.04$ already provides competitive constraints on the plane $[\tan \beta, m_{H^\pm}]$. The lattice techniques discussed in [66] promise precise calculations of m_c and m_s/m_c , which would further sharpen potential constraints from $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu/\tau^\pm \nu)$. We note that at a higher confidence level

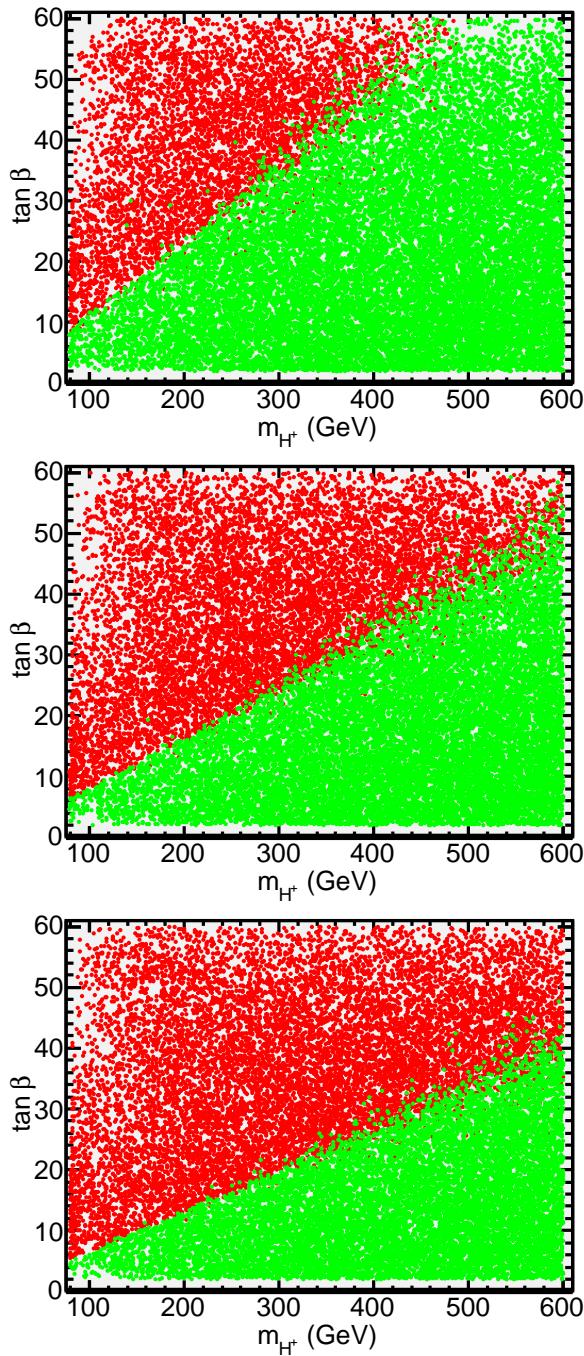

Figure 1: Constraints on the plane $[\tan \beta, m_{H^\pm}]$ from the decay $D_s^\pm \rightarrow \tau^\pm \nu$ for $m_s/m_c = 0.04, 0.08$ and 0.12 from top to bottom. Red points are excluded at 95% C.L.

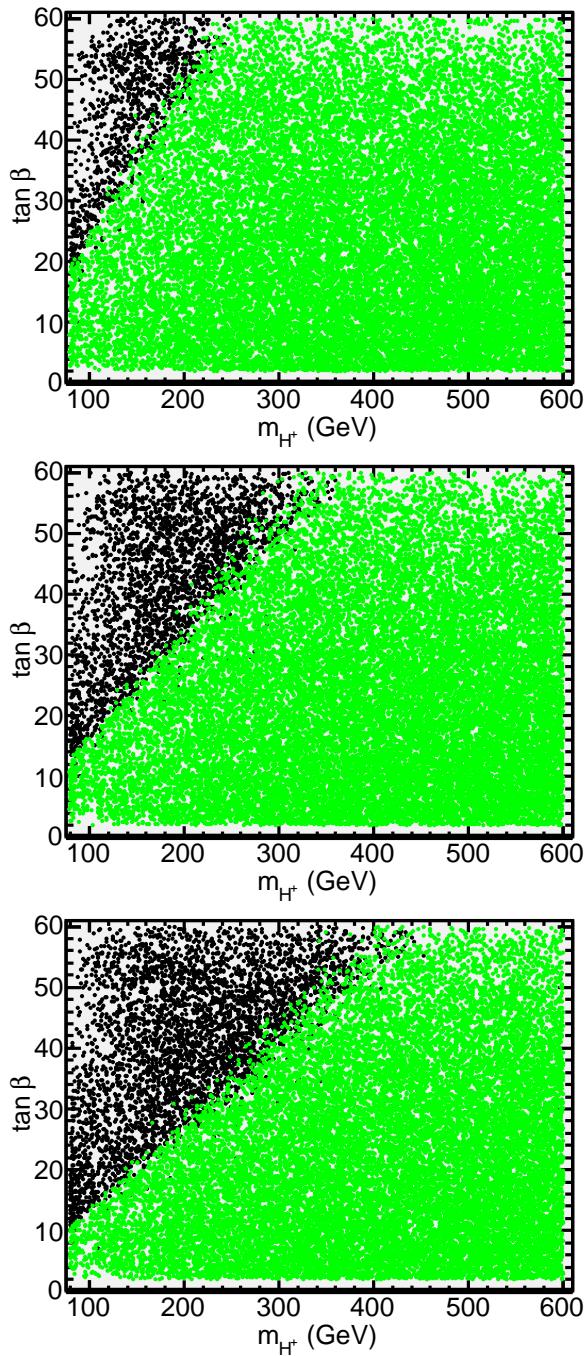

Figure 2: Constraints on the plane $[\tan \beta, m_{H^\pm}]$ from the decay $D_s^\pm \rightarrow \mu^\pm \nu$ for $m_s/m_c = 0.04, 0.08$ and 0.12 from top to bottom. Black points are excluded at 95% C.L.

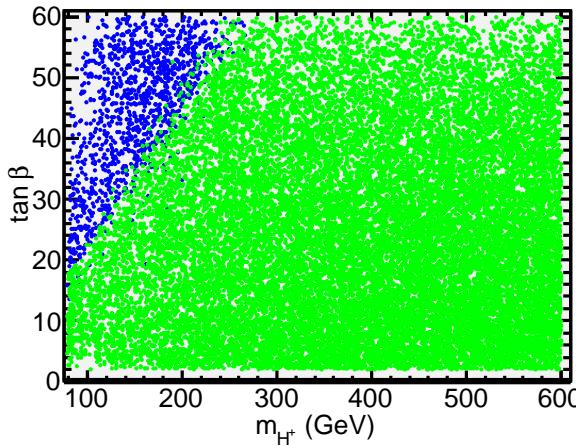

Figure 3: Constraints on the plane $[\tan \beta, m_{H^\pm}]$ from the observable $R_{\ell 23}$ (which involves $K^\pm \rightarrow \mu^\pm \nu / \pi^\pm \rightarrow \mu^\pm \nu$ decays). Blue points are excluded at 95% C.L.

(e.g., 99.7% C.L.) the constraints on the plane $[\tan \beta, m_{H^\pm}]$ from $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu / \tau^\pm \nu)$ are weaker than those from $R_{\ell 23}$ because the latter is measured more precisely.

As pointed out in [42], one of the virtues of $R_{\ell 23}$ is the fact that it can probe a region of plane $[\tan \beta, m_{H^\pm}]$ which cannot be probed by the decay $B^\pm \rightarrow \tau^\pm \nu$ (corresponding to the case of the H^\pm induced amplitude for $B^\pm \rightarrow \tau^\pm \nu$ being similar in size to that of the SM contribution but with opposite sign). We stress that $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ can exclude this parameter space with greater significance than $R_{\ell 23}$, using the lattice calculations of [50] for the SM prediction. Therefore both $D_s^\pm \rightarrow \tau^\pm \nu$ and $D_s^\pm \rightarrow \mu^\pm \nu$ offer constraints competitive with those of $R_{\ell 23}$ and complementary to those of $B^\pm \rightarrow \tau^\pm \nu$. Moreover, we note that the experimental prospects are more favourable for $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ and $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ than for $R_{\ell 23}$. The recently commenced BES-III experiment [12] aims to reduce the error of both $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu)$ and $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ to the level of a few percent (i.e. two to three times smaller than the current error) while a similar improvement for the precision of $R_{\ell 23}$ seems unlikely in the same time scale.

All the above numerical analysis has been performed with $f_{D_s} = 241 \pm 3$ MeV, and we now comment on the scenario of using a higher value of f_{D_s} with larger errors. Repeating the numerical analysis with $f_{D_s} = 248 \pm 3 \pm 8$ MeV [52] results in almost no constraints on the plane $[\tan \beta, m_{H^\pm}]$. This conclusion also applies to constraints derived from $R_{\ell 23}$ using calculations of f_K/f_π with a larger error (see section 2.2). Hence it is clear that strict constraints on the plane $[\tan \beta, m_{H^\pm}]$ from $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu_\tau / \mu^\pm \nu_\mu)$ and $R_{\ell 23}$ are strongly dependent on input from lattice QCD. However, their tree-level sensitivity to H^\pm makes them potentially valuable probes of the MSSM and 2HDM (Type II), despite the above reservations. Both $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu_\tau)$ and $\text{BR}(D_s^\pm \rightarrow \mu^\pm \nu_\mu)$ could start to play a significant role in constraining the plane $[\tan \beta, m_{H^\pm}]$ if future lattice calculations of f_{D_s} favour $f_{D_s} < 250$ MeV. Given the ongoing interest in calculating f_{D_s} in lattice QCD (summarized in [49]) and the timely commencement of the BES-III experiment, we

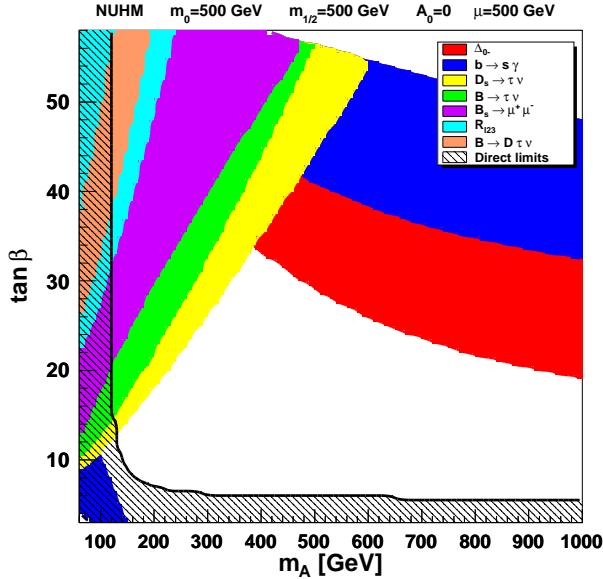

Figure 4: Regions of the plane $[\tan \beta, m_A]$ in the NUHM model excluded by different flavour observables. The constraints are superimposed in the order given in the legend.

emphasize that these decays should not be overlooked in phenomenological studies of H^\pm in the MSSM and 2HDM (Type II).

Finally we discuss the constraints on the plane $[\tan \beta, m_{H^\pm}]$ from B physics observables. As discussed in the introduction, one-loop induced decays such as $b \rightarrow s\gamma$ [67] and $B_s^0 \rightarrow \mu^+ \mu^-$ [68, 69] can give powerful constraints on the plane $[\tan \beta, m_{H^\pm}]$ (e.g. [21, 44, 70, 71, 72]) although with a stronger dependence on SUSY parameters than the purely leptonic decays discussed up to now. In Fig. 4 we present an example of the constraints obtained by different flavour observables (both tree-level and one-loop induced) for fixed values of $m_0 = m_{1/2} = \mu = 500$ GeV and $A_0 = 0$. We show the results in the plane $[\tan \beta, m_A]$, where m_A is the mass of the pseudoscalar which is very close in magnitude to m_{H^\pm} for $m_A > 200$ GeV. The regions excluded by $b \rightarrow s\gamma$ observables are displayed in red for the isospin asymmetry and in blue for the branching ratio [72, 73]. The region excluded by $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ is depicted in yellow. The green area represents the region excluded by $\text{BR}(B^\pm \rightarrow \tau^\pm \nu)$, the violet region by $\text{BR}(B_s^0 \rightarrow \mu^+ \mu^-)$, the light blue region by $K^\pm \rightarrow \mu^\pm \nu$, and the orange area by $\text{BR}(B \rightarrow D \tau \nu)$ [44], the latter also being sensitive at tree level to H^\pm and can provide constraints competitive with $\text{BR}(B^\pm \rightarrow \tau^\pm \nu)$ [18, 19, 20, 74, 75]. To obtain the constraints presented in this figure the input values of [41] are used. It is important to remember that the constraints can be subject to uncertainties, in particular from decay constants and CKM matrix elements. To obtain the constraint from $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ the central value $m_s/m_c = 0.08$ is used. Finally, the black region in the figure represents the region excluded by the direct searches at colliders [39]. This figure shows that $\text{BR}(D_s^\pm \rightarrow \tau^\pm \nu)$ can be very competitive with the other decays in the context of the NUHM.

4 Conclusions

Constraints on the parameter space of $[\tan \beta, m_{H^\pm}]$ have been derived from the effect of singly charged Higgs bosons on the decays $D_s^\pm \rightarrow \mu^\pm \nu_\mu$ and $D_s^\pm \rightarrow \tau^\pm \nu_\tau$ in the context of the Minimal Supersymmetric Standard Model. It was shown that such constraints can be competitive with and complementary to those derived from other flavour physics observables, especially if future lattice QCD calculations favour $f_{D_s} < 250$ MeV (which is already suggested by the result of [50]). We emphasize that such decays will be measured more precisely at the charm facility BES-III and hence could play an important role in constraining the plane $[\tan \beta, m_{H^\pm}]$ in the context of supersymmetric models in the future. The numerical analysis was performed by the publically available code SuperIso [40, 41] and we encourage the inclusion of $D_s^\pm \rightarrow \mu^\pm \nu_\mu$ and $D_s^\pm \rightarrow \tau^\pm \nu_\tau$ in other studies of flavour physics constraints on supersymmetric models.
